For example, applying the definition twice, we get

$$\begin{aligned} P(\mathrm{a}, \mathrm{b}, \mathrm{c}) &= P(\mathrm{a} \mid \mathrm{b}, \mathrm{c}) P(\mathrm{b}, \mathrm{c}) \\ P(\mathrm{b}, \mathrm{c}) &= P(\mathrm{b} \mid \mathrm{c}) P(\mathrm{c}) \\ P(\mathrm{a}, \mathrm{b}, \mathrm{c}) &= P(\mathrm{a} \mid \mathrm{b}, \mathrm{c}) P(\mathrm{b} \mid \mathrm{c}) P(\mathrm{c}). \end{aligned}$$

3.7 Independence and Conditional Independence

Two random variables x and y are **independent** if their probability distribution can be expressed as a product of two factors, one involving only x and one involving only y:

$$\forall x \in \mathrm{x}, y \in \mathrm{y},\ p(\mathrm{x} = x, \mathrm{y} = y) = p(\mathrm{x} = x) p(\mathrm{y} = y). \tag{3.7}$$

Two random variables x and y are **conditionally independent** given a random variable z if the conditional probability distribution over x and y factorizes in this way for every value of z:

$$\forall x \in \mathrm{x}, y \in \mathrm{y}, z \in \mathrm{z},\ p(\mathrm{x} = x, \mathrm{y} = y \mid \mathrm{z} = z) = p(\mathrm{x} = x \mid \mathrm{z} = z) p(\mathrm{y} = y \mid \mathrm{z} = z). \tag{3.8}$$

We can denote independence and conditional independence with compact notation: $\mathrm{x} \perp \mathrm{y}$ means that x and y are independent, while $\mathrm{x} \perp \mathrm{y} \mid \mathrm{z}$ means that x and y are conditionally independent given z.

3.8 Expectation, Variance and Covariance

The **expectation** or **expected value** of some function $f(x)$ with respect to a probability distribution $P(\mathrm{x})$ is the average or mean value that f takes on when x is drawn from P. For discrete variables this can be computed with a summation:

$$\mathbb{E}_{\mathrm{x} \sim P}[f(x)] = \sum_x P(x) f(x), \tag{3.9}$$

while for continuous variables, it is computed with an integral:

$$\mathbb{E}_{\mathrm{x} \sim p}[f(x)] = \int p(x) f(x) dx. \tag{3.10}$$
