$$\boldsymbol{x} = \boldsymbol{A}^{-1}\boldsymbol{b}. \tag{2.25}$$

Of course, this process depends on it being possible to find $\boldsymbol{A}^{-1}$. We discuss the conditions for the existence of $\boldsymbol{A}^{-1}$ in the following section.

When $\boldsymbol{A}^{-1}$ exists, several different algorithms exist for finding it in closed form. In theory, the same inverse matrix can then be used to solve the equation many times for different values of $\boldsymbol{b}$. However, $\boldsymbol{A}^{-1}$ is primarily useful as a theoretical tool, and should not actually be used in practice for most software applications. Because $\boldsymbol{A}^{-1}$ can be represented with only limited precision on a digital computer, algorithms that make use of the value of $\boldsymbol{b}$ can usually obtain more accurate estimates of $\boldsymbol{x}$.

2.4 Linear Dependence and Span

In order for $\boldsymbol{A}^{-1}$ to exist, equation 2.11 must have exactly one solution for every value of $\boldsymbol{b}$. However, it is also possible for the system of equations to have no solutions or infinitely many solutions for some values of $\boldsymbol{b}$. It is not possible to have more than one but less than infinitely many solutions for a particular $\boldsymbol{b}$; if both $\boldsymbol{x}$ and $\boldsymbol{y}$ are solutions then

$$\boldsymbol{z} = \alpha\boldsymbol{x} + (1-\alpha)\boldsymbol{y} \tag{2.26}$$

is also a solution for any real α.

To analyze how many solutions the equation has, we can think of the columns of $\boldsymbol{A}$ as specifying different directions we can travel from the **origin** (the point specified by the vector of all zeros), and determine how many ways there are of reaching $\boldsymbol{b}$. In this view, each element of $\boldsymbol{x}$ specifies how far we should travel in each of these directions, with x_i specifying how far to move in the direction of column i:

$$\boldsymbol{A}\boldsymbol{x} = \sum_i x_i \boldsymbol{A}_{:,i}. \tag{2.27}$$

In general, this kind of operation is called a **linear combination**. Formally, a linear combination of some set of vectors $\{\boldsymbol{v}^{(1)}, \ldots, \boldsymbol{v}^{(n)}\}$ is given by multiplying each vector $\boldsymbol{v}^{(i)}$ by a corresponding scalar coefficient and adding the results:

$$\sum_i c_i \boldsymbol{v}^{(i)}. \tag{2.28}$$

The **span** of a set of vectors is the set of all points obtainable by linear combination of the original vectors.
